Management of Unanticipated Difficult Airway in the Prehospital Emergency Setting

To the Editor:

We were greatly interested in the recent article of Combes et al. that prospectively validated a prehospital difficult-intubation algorithm. In this clinical study, the tracheal intubation with direct laryngoscope proved impossible in 160 patients. However, of these 160 patients, 15 had a laryngeal view of the Cormack and Lehane (C&L) class I or II, which is generally regarded as an easy laryngoscopy. Moreover, the authors did not clearly state the type of the ILMA used for this difficult-intubation management algorithm. When an ILMA is used as a rescue device in the prehospital setting, we recommend use of the ILMA CTrach™ (Laryngeal Mask Company Limited, San Diego, CA) with the integrated fiber-optic channels and a detachable liquid crystal display viewer, rather than the ILMA Fastrach™ (Laryngeal Mask Company Limited). It has been shown that compared with the ILMA Fastrach™, the ILMA CTrach™ can enable a higher first-attempt success rate of tracheal intubation because of the view of the glottis it provides, the way it optimizes placement of the device, the ability to observe the process of tracheal intubation through the above objective mark (e.g., C&L class IV), blindly inserting the GEB into the trachea will be very difficult. In clinical practice, the GEB-guided intubation is really the most suitable for patients with a C&L class less than IV. Thus, we consider that in their difficult-intubation management algorithm, the rescue step to use the GEB-guided intubation as first choice may be suitable only for the patients with a C&L class less than IV. After a single intubation attempt failed in patients with a C&L class IV, the rescue airway algorithm should move directly to the step that uses the ILMA to ventilate the patients and then to intubate the trachea, but not to the step that attempts reintubation with the GEB because it has high risks of failed intubation and increased airway trauma. For this situation, we completely agree with the editorial view of Drs. Isono and Ishikawa that maintenance of oxygenation is the final goal of airway management.

The authors did not clearly state the type of the ILMA used for this difficult-intubation management algorithm. When an ILMA is used as a rescue device in the prehospital setting, we recommend use of the ILMA CTrach™ (Laryngeal Mask Company Limited, San Diego, CA) with the integrated fiber-optic channels and a detachable liquid crystal display viewer, rather than the ILMA Fastrach™ (Laryngeal Mask Company Limited). It has been shown that compared with the ILMA Fastrach™, the ILMA CTrach™ can enable a higher first-attempt success rate of tracheal intubation because of the view of the glottis it provides, the way it optimizes placement of the device, and the ability to observe the process of tracheal intubation through the device. In addition, data from the study of Nickel et al. suggest that the ILMA CTrach™ is a suitable device for emergency airway management in the prehospital setting because it provides ventilation and facilitates intubation with a very high success rate.

In Reply:

We thank very much Xue et al., for their interesting letter concerning our recently published article in Anesthesiology.1 The remarks and questions are important and need some clarifications. Concerning the patients with Cormack and Lehane class I or II, it is right that most often these patients are, and were in our series, easy to intubate. But sometimes, as outlined by Xue et al., the ease of direct laryngoscopy is not synonymous with ease of tracheal intubation. We encountered a difficult intubation in only 15 patients without any specific causes for their initial intubation failure.

Concerning the use of a stylet, our algorithm did not require the use of this device. We think that the gum elastic bougie (GEB) is more efficient and less traumatic than a stylet. We do not totally agree with Xue et al. that when the speed of tracheal intubation is important, a stylet should always be used. To our knowledge, no high-evidence-level studies support this statement. In the few studies that compared the stylet to the GEB, the GEB was more efficient and allowed intubation with a shorter time than did the stylet in difficult intubations.2,3 It is right that GEB is classically indicated only when the Cormack and Lehane class of laryngeal view is less than IV. However, we have already reported the potential interest of using GEB in patients with Cormack and Lehane class IV with a high intubation success rate.4

In our study, we used the reusable form of intubating Laryngeal Mask Airway (LMA) Fastrach™ (Laryngeal Mask Company Limited, San Diego, CA), not the intubating LMA CTTrach™. We agree with Xue et al. that the intubating LMA CTTrach™ is an excellent device and could have been used in our algorithm as a substitute for the intubating LMA Fastrach™. However, it has been reported that intubation through the intubating LMA CTTrach™ needs more time than does intubation using the intubating LMA Fastrach™.5 Moreover, the cost effectiveness of the intubating LMA CTTrach™ is questionable when compared with that of the intubating LMA Fastrach™.

A Modified Difficult Airway Management Algorithm Incorporating Video Devices in Routine Anesthesia Practice

To the Editor:
The recent article of Amathieu et al.1 that prospectively validated a modified difficult airway management algorithm incorporating video devices in routine anesthesia practice was of great interest to us. The authors should be congratulated for their excellent works in such a large cohort of anesthetized, paralyzed patients. However, there are several aspects of this study that should be clarified and discussed. We believe that such information would be helpful for others who would like to try this modified difficult airway management algorithm.

First, because authors did not provide the method of anesthesia induction used in this study, it was not clear whether the spontaneous breathing ceased when assessing facemask ventilation (FMV) before giving muscle relaxant in all patients with fewer than three adverse predictors. Moreover, if the amount of anesthetic is inadequate, airway spasm, a common cause of difficult FMV, can occur in response to irritation of the epiglottis and glottis from oropharyngeal or naso-
